Set the security level in the "Security" section to "No security.Q: Why are the outputs of the Gamma distribution and exponential distribution different? the outputs of a Gamma distribution are $y \sim \text{Gamma}(\alpha, \beta)$ and when the shape parameter is 1 the outcome must be exponentially distributed. But the PDF of the Gamma distribution is a shifted version of the PDF of the exponential distribution. There are two questions: 1) Why does the Gamma distribution have this relationship with the exponential distribution? 2) Why is it not possible to determine if a non-integer number of observations is being sampled from a Gamma distribution with just the shape parameter? A: To answer the first question, let's first look at the relation between the two distributions. The density of the Gamma (α, β) distribution is $f_{\text{Gamma}}(y \mid \alpha, \beta) = \frac{\beta^\alpha}{\Gamma(\alpha)} y^{\alpha-1} e^{-\beta y}$, $y \geq 0$
